

Cellular senescence is a leading cause of collagen production decline

It has long been known that extrinsic factors play a role in collagen degradation. For example, sun exposure triggers the production of collagen-degrading enzymes called matrix metalloproteinases (MMPs). Additionally, the reduced mechanical tension caused by damaged collagen hinder the efficient creation of new collagen by fibroblasts.⁰²

More recently, scientists have discovered that intrinsic factors, such as cellular senescence, also plays a significant role in the decline of collagen synthesis. In fact, research shows that collagen production in individuals over 80 is only 25% of that in young adults, with fibroblast senescence accounting for 45% of the decrease.⁰²
